

## FEATURES

### Isolated high-side and low-side outputs

High side or low side relative to input:  $\pm 700 V_{PEAK}$

High-side/low-side differential:  $700 V_{PEAK}$

### 0.1 A peak output current

### High frequency operation: 5 MHz maximum

### High common-mode transient immunity: $>75 \text{ kV}/\mu\text{s}$

### High temperature operation: $105^\circ\text{C}$

### Wide body, 16-lead SOIC

### Safety and regulatory approvals

#### UL recognition

2500 V rms for 1 minute per UL 1577

#### VDE certificate of conformity

DIN V VDE V 0884-10 (VDE V 0884-10): 2006-12

$V_{IORM} = 560 \text{ V peak}$

## APPLICATIONS

### Isolated IGBT/MOSFET gate drives

### Plasma displays

### Industrial inverters

### Switching power supplies

## GENERAL DESCRIPTION

The ADuM1233<sup>1</sup> is an isolated, half-bridge gate driver that uses the Analog Devices, Inc., *iCoupler*® technology to provide independent and isolated high-side and low-side outputs. Combining high speed CMOS and monolithic transformer technology, this isolation component provides outstanding performance characteristics superior to optocoupler-based solutions.

By avoiding the use of LEDs and photodiodes, this *iCoupler* gate drive device is able to provide precision timing characteristics not possible with optocouplers. Furthermore, the reliability and performance stability problems associated with optocoupler LEDs are avoided.

In comparison to gate drivers that use high voltage level translation methodologies, the ADuM1233 offers the benefit of true, galvanic isolation between the input and each output. Each output can be operated up to  $\pm 700 V_{PEAK}$  relative to the input, thereby supporting low-side switching to negative voltages. The differential voltage between the high side and low side can be as high as  $700 V_{PEAK}$ .

As a result, the ADuM1233 provides reliable control over the switching characteristics of IGBT/MOSFET configurations over a wide range of positive or negative switching voltages.

<sup>1</sup> Short-circuit duration less than one second.

<sup>2</sup> The minimum pulse width is the shortest pulse width at which the specified timing parameters are guaranteed.

<sup>3</sup> The maximum switching frequency is the maximum signal frequency at which the specified timing parameters are guaranteed.

<sup>4</sup>  $t_{PHL}$  propagation delay is measured from the 50% level of the falling edge of the  $V_{ix}$  signal to the 50% level of the falling edge of the  $V_{Ox}$  signal.  $t_{PLH}$  propagation delay is measured from the 50% level of the rising edge of the  $V_{ix}$  signal to the 50% level of the rising edge of the  $V_{Ox}$  signal.

<sup>5</sup> Channel-to-channel matching, rising or falling edges is the magnitude of the propagation delay difference between two channels of the same part when the inputs are either both rising or falling edges. The supply voltages and the loads on each channel are equal.

<sup>6</sup> Channel-to-channel matching, rising vs. falling edges is the magnitude of the propagation delay difference between two channels of the same part when one input is a rising edge and the other input is a falling edge. The supply voltages and loads on each channel are equal.

<sup>4</sup> Refers to common-mode transients across any insulation barrier. Common-mode transients exceeding the Absolute Maximum Ratings may cause latch-up or permanent damage.

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD CAUTION

**ESD (electrostatic discharge) sensitive device.** Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

# APPLICATIONS INFORMATION

## COMMON-MODE TRANSIENT IMMUNITY

In general, common-mode transients consist of linear and sinusoidal components. The linear component of a common-mode transient is given by

$$V_{CM, linear} = (\Delta V/\Delta t) t$$

where  $\Delta V/\Delta t$  is the slope of the transient shown in Figure 12 and Figure 13.

The transient of the linear component is given by

$$dV_{CM}/dt = \Delta V/\Delta t$$

The ability of the ADuM1233 to operate correctly in the presence of linear transients is characterized by the data in Figure 9. The data is based on design simulation and is the maximum linear transient magnitude that the ADuM1233 can tolerate without an operational error. This data shows a higher level of robustness than what is listed in Table 6 because the transient immunity values obtained in Table 6 use measured data and apply allowances for measurement error and margin.

Figure 9. Transient Immunity (Linear Transients) vs. Temperature

The sinusoidal component (at a given frequency) is given by

$$V_{CM, sinusoidal} = V_o \sin(2\pi ft)$$

where:

$V_o$  is the magnitude of the sinusoidal.

$f$  is the frequency of the sinusoidal.

The transient magnitude of the sinusoidal component is given by

$$dV_{CM}/dt = 2\pi f V_o$$

The ability of the ADuM1233 to operate correctly in the presence of sinusoidal transients is characterized by the data in Figure 10 and Figure 11. The data is based on design simulation and is the maximum sinusoidal transient magnitude ( $2\pi f V_o$ ) that the ADuM1233 can tolerate without an operational error. Values for immunity against sinusoidal transients are not included in Table 6 because measurements to obtain such values have not been possible.
